The MODBUS Slave driver is a TCP/IP 4.5.x based program that is a socket server, which is a software component which runs on an entity's computer, and accepts connections from other entities running on other computers. By default, MODBUS TCP/IP slaves are available only via the modem if this has been turned on. Users can add slave devices by manually specifying IP/TCP addresses and port ranges which can be dynamically allocated to a group of slave devices. A MODBUS Slave device consists of a slave (Remote Terminal Unit) and a master (Controller). The slave contains the application program which is accessed by the master using its network connection. The slave may be able to run multiple instances of the same application program concurrently. A master may consist of a Control Program (CP) and a Control List Program (CLP). A Control Program usually takes the form of a special-purpose software application or service which is used to control and monitor the operation of other Control Programs. A Control List usually consists of a sequence of commands which may be applied to the slave to control and monitor the operation of the slave. MODBUS 3.0 can be used to develop Multi-Channel applications on a Windows OS. The multi-channel functionality can allow these applications to communicate over a network. The multi-channel functionality can allow these applications to be used over a Modbus RTU network. MODBUS 2.1 and 2.0 are the last editions of the protocol. MODBUS 2.1 complies with the recommendation of the Working Group on Distributed Computing Environment (WGDC). MODBUS 2.0/2.1 are almost compatible with each other. The main difference is that MODBUS 2.1 is compliant with the WGDC recommendation. This means that the protocol is backwardly compatible with respect to the last version 2.0 and that the newer features are the same as in MODBUS 2.1.

The ReadRegister and WriteRegister functions can be used for communication between a client and a master on a Modbus TCP/IP network, allowing a process to read and write data over the network in a timely manner. Modbus TCP/IP is an open standard for a reliable and secure communication over IP networks. Modbus TCP/IP messages are transported via TCP/IP using the OSI layer two (Data Link Layer) (transport layer) which is specified in the TCP/IP specifications of RFC793, RFC1144, RFC1122, RFC1123. The actual implementation of the transport layer is realized through the Modbus TCP driver Control Techniques. Modbus TCP protocol has been developed by Control Techniques in 1999. It has been standardized by the international Modbus TCP Consortium. Modbus TCP provides a simple, low-level transport for real-time data communication with industry-standard TCP/IP network infrastructure. Systems that speak Modbus can be easily added as Modbus TCP clients to a Modbus TCP server. Modbus TCP is an open standard for a reliable and secure communication over IP networks. The actual implementation of the transport layer is realized through the Modbus TCP driver Control Techniques. The Modbus Driver and Library enable a .NET application to communicate with Modbus devices. The simplicity of the API makes it easy for a developer to integrate Modbus into an application, regardless of the application's original implementation. The library provides Modbus TCP/IP over TCP/IP connections to be used as an alternative to Modbus TCP in most cases. Sec8ef588b
